

LM3103 Demonstration Board Reference Design

National Semiconductor
Application Note 1678
LK Wong
October 2007

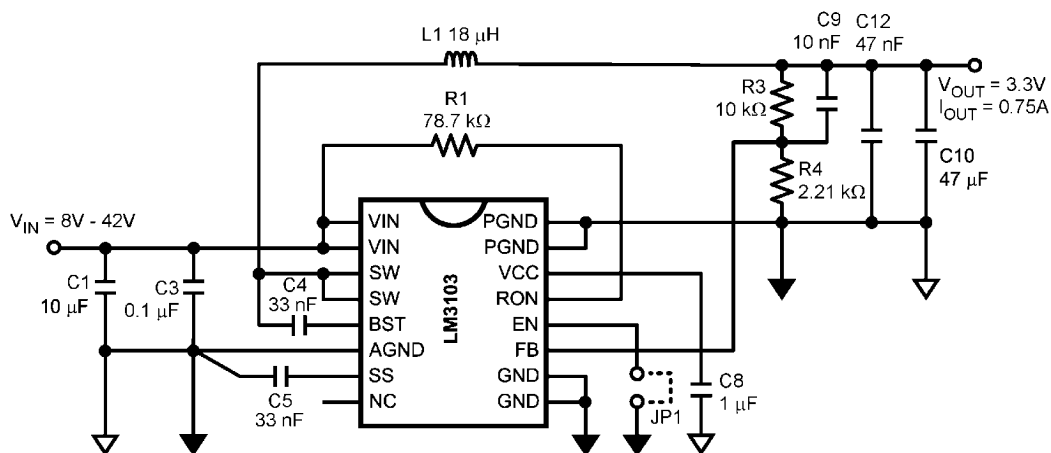

Introduction

The LM3103 Step Down Switching Regulator features all required functions to implement a cost effective, efficient buck power converter capable of supplying 0.75A to loads. The Constant On-Time (COT) regulation scheme requires no loop compensation, results in a fast load transient response and simple circuit implementation which allows a low component count, and consequently very small overall board space is required for a typical application. The regulator can function properly even with an all ceramic output capacitor network, and does not rely on the output capacitor's ESR for stability. The operating frequency remains constant with line variations

due to the inverse relationship between the input voltage and the on-time. Protection features include output over-voltage protection, thermal shutdown, V_{CC} under-voltage lock-out, gate drive under-voltage lock-out. The LM3103 is available in the thermally enhanced eTSSOP-16 package.

This application note details the design of a demonstration board which provides a 3.3V output voltage with 0.75A load capability for a wide input voltage range from 8V to 42V. The demonstration board schematic, PCB layout, Bill of Materials, and circuit design descriptions are shown. Typical performance and operating waveforms are also provided for reference.

Demonstration Board Quick Setup Procedures

Step	Description	Notes
1	Connect a power supply to VIN terminals	V_{IN} range: 8V to 42V
2	Connect a load to VOUT terminals	I_{OUT} range: 0A to 0.75A
3	SD (JP1) should be left open for normal operation. Short this jumper to shutdown	
4	Set $V_{IN} = 18V$, with 0A load applied, check V_{OUT} with a voltmeter	Nominal 3.3V
5	Apply 0.75A load and check V_{OUT}	Nominal 3.3V
6	Short output terminals and check the short circuit current with an ammeter	Nominal 1.05A
7	Short SD (JP1) to check the shutdown function	

Demonstration Board Performance Characteristic

Description	Symbol	Condition	Min	Typ	Max	Unit
Input Voltage	V_{IN}		8	18	42	V
Output Voltage	V_{OUT}		3.2	3.3	3.4	V
Output Current	I_{OUT}		0	-	0.75	A
Output Voltage Ripple	$V_{OUT(Ripple)}$		-	-	50	mVp-p
Output Voltage Regulation	ΔV_{OUT}	ALL V_{IN} and I_{OUT} Conditions	-2		+2	%
Efficiency		$V_{IN} = 8V$	85		91	%
		$V_{IN} = 24V$	71		84	%
		$V_{IN} = 42V$ ($I_{OUT} = 0.1A$ to $0.75A$)	59		78	%
Output Short Current Limit	I_{LIM-SC}			1.05		A

Design Procedure

The LM3103 is easy to use compared with other devices available on the market because it integrates all key components, including both the main and synchronous power MOSFETs, in a single package and requires no loop compensation owing to the use of the Constant On-Time (COT) hysteretic control scheme. The design of the demonstration board in this application note is detailed below.

Design Parameters:

$V_{IN} = 8V$ to $42V$, typical $18V$

$V_{OUT} = 3.3V$

$I_{OUT} = 0.75A$

Step 1: Calculate the feedback resistors

The ratio of the feedback resistor can be calculated from the following equation:

$$\frac{R3}{R4} = \frac{V_{OUT}}{0.6} - 1$$

As a general practice, R3 and R4 should be chosen from standard 1% resistor values in the range of $1.0\text{ k}\Omega$ to $10\text{ k}\Omega$ satisfying the above ratio. Now, select $R3 = 10\text{ k}\Omega$, with $V_{OUT} = 3.3V$,

$$R4 = \frac{10\text{ k}\Omega}{\left(\frac{V_{OUT}}{0.6} - 1\right)} = 2.22\text{ k}\Omega$$

Step 2: Calculate the on-time setting resistor

The switching frequency f_{SW} of the demonstration board is affected by the on-time t_{on} of the LM3103, which is determined by R1. If f_{SW} and V_{OUT} are determined, R1 can be calculated as follows:

$$R1 = \frac{V_{OUT}}{8.3 \times 10^{-11} \times f_{SW}}$$

For this demonstration board design, $V_{OUT} = 3.3V$ and $f_{SW} = 500\text{ kHz}$ are chosen. As a result, $R1 = 78.52\text{ k}\Omega$. To ensure that the on-time is larger than the minimum limit, which is 100 ns , the value of R1 must satisfy the following equation:

$$R1 \geq \frac{V_{IN(MAX)} \times 100\text{ ns}}{8.3 \times 10^{-11}}$$

Now the maximum V_{IN} is $42V$, the calculated R1 satisfies the above equation.

Step 3: Determine the inductance

The main parameter affected by the inductor is the amplitude of the inductor current ripple I_{LR} . Once I_{LR} is selected, L1 can be determined by:

$$L1 = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{I_{LR} \times f_{SW} \times V_{IN}}$$

For this demonstration board design, $I_{LR} = 0.3A$ is selected. Now $V_{IN} = 18V$, $V_{OUT} = 3.3V$, and $f_{SW} = 500\text{ kHz}$. As a result, $L = 17.97\text{ }\mu\text{H}$.

Inductor Selection for $V_{OUT} = 3.3V$

30028810

Step 4: Determine the value of other components

C1: The function of C1 is to supply most of the main MOSFET current during the on-time, and limit the voltage ripple at the VIN pin, assuming that the voltage source connecting to the VIN pin has finite output impedance. If the voltage source's dynamic impedance is high (effectively a current source), C1 supplies the average input current, but not the ripple current. At the maximum load current, when the main MOSFET turns on, the current to the VIN pin suddenly increases from zero to the lower peak of the inductor's ripple current and ramps up to the higher peak value. It then drops to zero at turn-off. The average current during the on-time is the load current. For a worst case calculation, C1 must be capable of supplying this average load current during the maximum on-time. C1 is calculated from:

$$C1 = \frac{I_{OUT} \times t_{on}}{\Delta V_{IN}}$$

where I_{OUT} is the load current, t_{on} is the maximum on-time, and ΔV_{IN} is the allowable ripple voltage at V_{IN} . In this demonstration board, a $10\text{ }\mu\text{F}$ capacitor is used.

C3: C3's purpose is to help avoid transients and ringing due to long lead inductance at the VIN pin. A low ESR $0.1\text{ }\mu\text{F}$ ceramic chip capacitor located close to the LM3103 is used in this demonstration board.

C4: A 33 nF high quality ceramic capacitor with low ESR is used for C4 since it supplies a surge current to charge the main MOSFET gate driver at turn-on. Low ESR also helps ensure a complete recharge during each off-time.

C5: The capacitor at the SS pin determines the soft-start time, i.e. the time for the reference voltage at the regulation comparator and the output voltage to reach their final value. The soft-start time is affected by the output capacitor, which can lengthen the time, and the charging of C5. The minimum soft-start time is determined by the following equation:

$$t_{ss} > 180\text{ }\mu\text{s} + \frac{C5 \times 0.6V}{70\text{ }\mu\text{A}}$$

In this demonstration board, a 33 nF capacitor is used for C5, and the corresponding soft-start time is about $600\text{ }\mu\text{s}$.

C8: The capacitor on the V_{CC} output provides not only noise filtering and stability, but also prevents false triggering of the V_{CC} UVLO at the main MOSFET on/off transitions. C8 should be no smaller than 1 μ F for stability, and should be a good quality, low ESR, ceramic capacitor.

C9: If the output voltage is higher than 1.6V, C9 is needed in the Discontinuous Conduction Mode to reduce the output ripple. In this demonstration board, a 10 nF capacitor is used.

C10: The output capacitor should generally be no smaller than 10 μ F. Experiment is usually necessary to determine the minimum value for the output capacitor, as the nature of the load may require a larger value. A load which creates significant transients requires a larger output capacitor than a fixed load. In this demonstration board, a 47 μ F capacitor is used to provide a low output ripple.

C12: C12 is a small value ceramic capacitor located close to the LM3103 to further suppress high frequency noise at V_{OUT} . A 47 nF capacitor is used in this demonstration board.

PC Board Layout

The LM3103 regulation, over-voltage, and current limit comparators are very fast so they will respond to short duration noise pulses. Layout is therefore critical for optimum performance. It must be as neat and compact as possible, and all external components must be as close to their associated pins of the LM3103 as possible. The loop formed by C1, the main and synchronous MOSFET internal to the LM3103, and the PGND pin should be as small as possible. The connection

from the PGND pin to the input capacitors should be as short and direct as possible. Vias should be added to connect the ground of the input capacitors to a ground plane, located as close to the capacitor as possible. The bootstrap capacitor C4 should be connected as close to the SW and BST pins as possible, and the connecting traces should be thick. The feedback resistors and capacitor R3, R4, and C9 should be close to the FB pin. A long trace running from V_{OUT} to R3 is generally acceptable since this is a low impedance node. Ground R4 directly to the AGND pin (pin 7). The output capacitor C10 should be connected close to the load and tied directly to the ground plane. The inductor L1 should be connected close to the SW pin with as short a trace as possible to reduce the potential for EMI (electromagnetic interference) generation. If it is expected that the internal dissipation of the LM3103 will produce excessive junction temperature during normal operation, making good use of the PC board's ground plane can help considerably to dissipate heat. The exposed pad on the bottom of the LM3103 IC package can be soldered to the ground plane, which should extend out from beneath the LM3103 to help dissipate heat. The exposed pad is internally connected to the LM3103 IC substrate. Additionally the use of thick traces, where possible, can help conduct heat away from the LM3103. Using numerous vias to connect the die attached pad to the ground plane is a good practice. Judicious positioning of the PC board within the end product, along with the use of any available air flow (forced or natural convection) can help reduce the junction temperature.
